

End-to-end OFDIM system using KDML

EECS 555

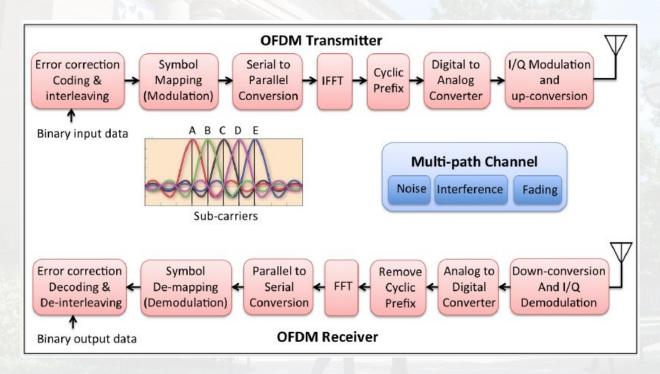

Goals

- Implement an end-to-end OFDM system for Tx and Rx using USRP X310 and GNU Radio
- Use python code to write all components of the system, and build a Deep Learning based complete receiver that does joint channel estimation and symbol detection.
- Built a model to obtain an estimate of the channel response using Super Resolution and Image Restoration Neural Networks.

OFDM

- Is a digital multi-carrier modulation scheme that extends the concept of single subcarrier modulation by using multiple subcarriers within the same single channel.
- Multiple orthogonal subcarriers carry the information stream resistant to frequency selective fading than single carrier systems.
- Each subcarrier is modulated with a conventional digital modulation scheme (such as QPSK, 16QAM, etc.) at low symbol rate.

OFDM

Disadvantages of OFDM

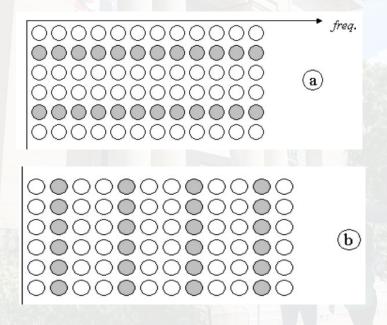

- OFDM signals have noise like amplitude variation and has a relatively high large dynamic range, or peak to average power ratio.
- It is sensitive to carrier frequency offset and drift. Single carrier systems are less sensitive.

Types of OFDM Models Designed

Based on the type of Channel we modelled, we tried modelling two different OFDM systems:

- 1. Block Type Pilot arrangement
 - For Slow Fading Channels
 - Here we modelled the data to be in sequential.
- 2. Comb Type Pilot arrangement
 - For Fast Fading Channels
 - Here we are sending block streams of data to the Channel.

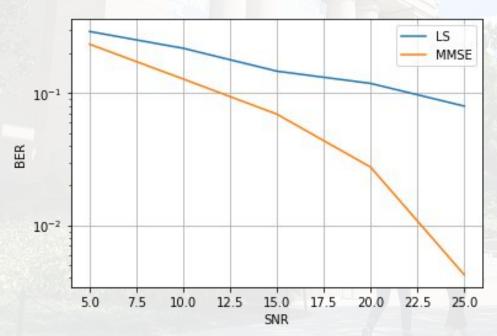

Types of Pilots we used

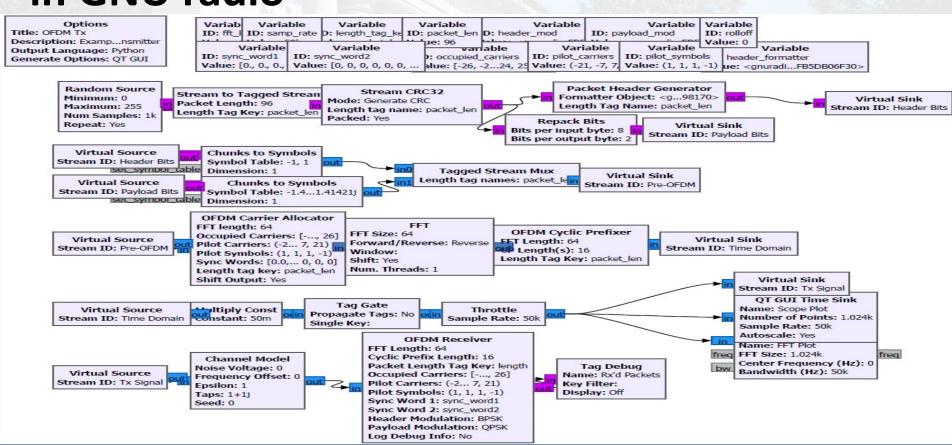

Block Type

Comb Type

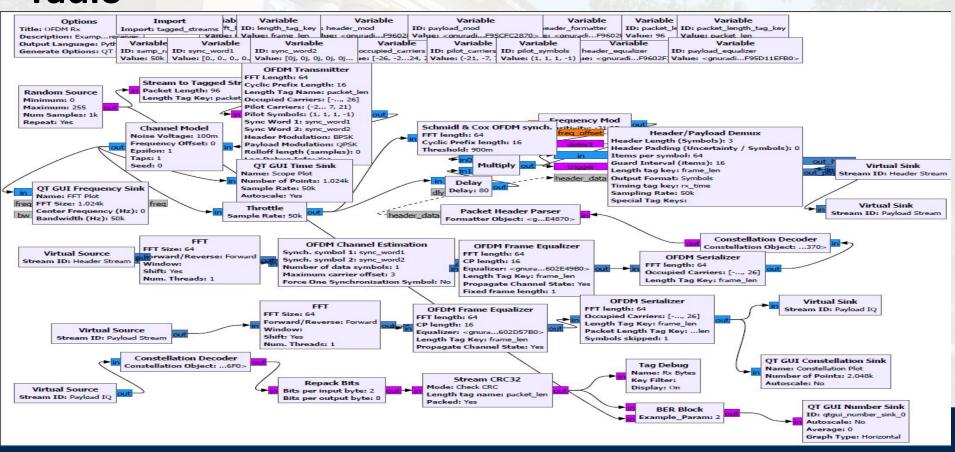

Results for General OFDM System with High Delay Spread

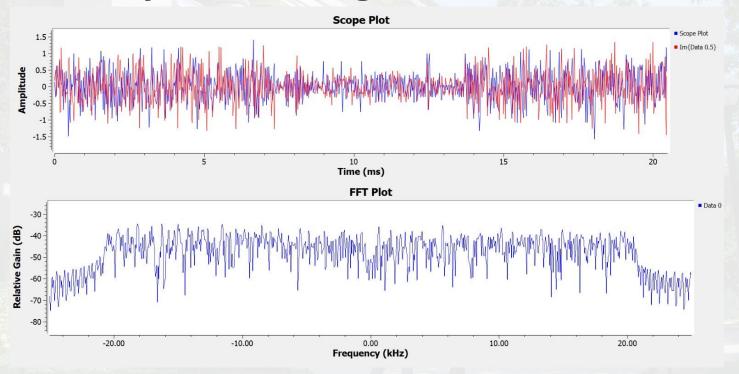

End to end OFDM system implementation in GNU radio

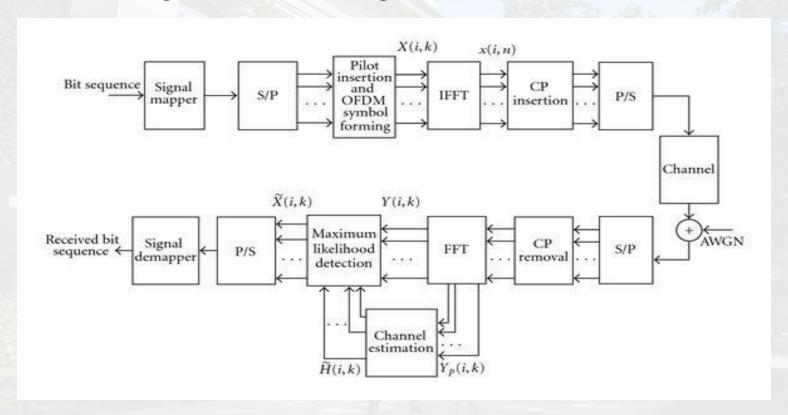

End to end OFDM system implementation in GNU radio

OFDM system using USRP/ GNU Radio

OFDM System in Python

Channel Model

We chose to model our channel with Rician fading (LOS included).

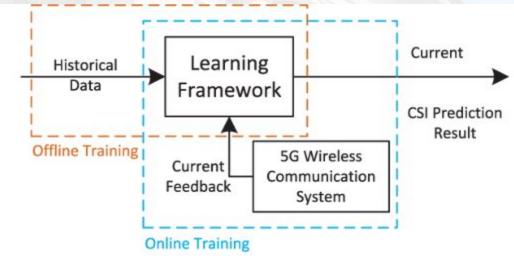

$$\tilde{a}_n(t) = a_n(t) \exp \left[-j2\pi f_c T_n(t)\right]$$

$$h(t, T) = \sum_{n} \tilde{a}_{n}(t) \delta(t - T_{n}(t))$$

Channel Model

```
def generate random_taps(self, nsymbol):
   for i in range(self.no taps):
       list rx = [np.random.uniform(0,1) for i in range(self.no taps-1)]
       list rx=np.sort(list rx)
       tou= np.hstack((0,list rx))
        ray= np.hstack((1,np.random.rayleigh(0.5, self.no_taps-1)))
        self.channelResponse[nsymbol, i] = ray[i]*np.exp(-1j*2*self.center_freq*tou[i])
   self.H_exact[nsymbol, :] = np.fft.fft(self.channelResponse[nsymbol,:], self.K)
```

Using Machine Learning

Our problem statement: Due to increasing complexity of wireless communication scenarios, tracking precise channel state information (CSI) is crucial.

Conventional Channel Estimation

OFDM uses the reference signal based estimation courtesy of pilot symbols and performs channel estimation.

Primarily two conventional estimation methods:

- LS algorithm
- MMSE

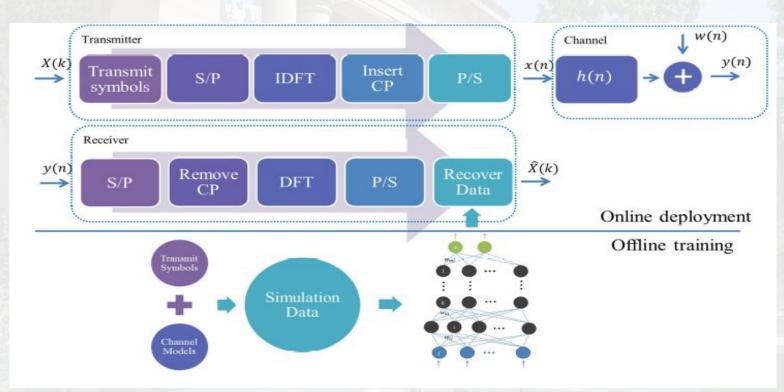

LS has simple structure and low complexity characteristics but its performance is not satisfactory. MMSE uses the prior knowledge to improve its performance but the complexity is too high.

LS and MMSE Estimation

```
def channelEstimate(self, OFDM demod):
    pilots = OFDM_demod[self.pilotCarriers]
     # extract the pilot values from the RX signal
   Hest_at_pilots = pilots / self.pilotValue
    Hest abs = scipy.interpolate.interp1d(self.pilotCarriers,
     abs(Hest at pilots), kind='linear')(self.allCarriers)
   Hest phase = scipy.interpolate.interp1d(self.pilotCarriers,
    np.angle(Hest_at_pilots), kind='linear')(self.allCarriers)
   Hest = Hest_abs * np.exp(1j*Hest_phase)
    return Hest
```

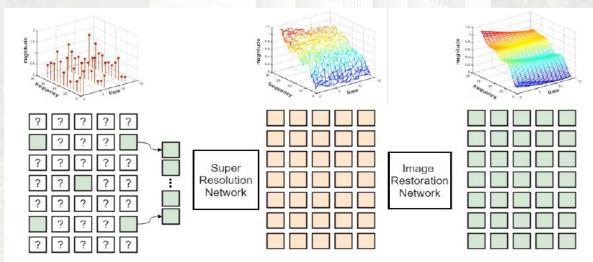

```
def MMSE channelEstimate(self, OFDM demod, nsymbol):
    # import pdb;pdb.set trace()
    C_response = np.array(self.H_exact[nsymbol,:]).reshape(-1,1)
    C_response_H = np.conj(C_response).T
    R HH = np.matmul(C response, C response H)
    snr = 10**(self.SNRdb/10)
    # W = R HH/(R HH+(self.beta/snr)*np.eye(self.K))
    W = np.matmul(R HH,np.linalg.inv((R HH+(self.beta/snr)*np.eye(self.K))))
    HhatLS = self.channelEstimate(OFDM demod)
    HhatLS = HhatLS.reshape(-1,1)
    HhatLMMSE = np.matmul(W, HhatLS)
    return HhatLMMSE.squeeze()
```

Model 1

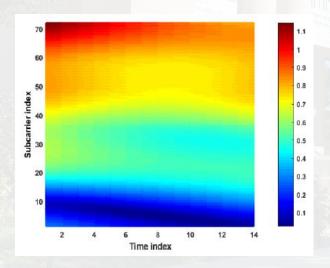

Model 2

This scheme considers the pilot values, altogether, as a low-resolution image and uses an SR network cascaded with a denoising IR network to estimate the channel.

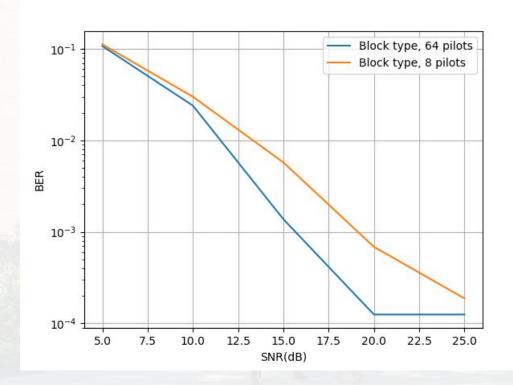

Model 2

For this link, the channel time-frequency response matrix H (of size N_S x N_D) between Tx and Rx which has complex values, are as two 2D-images (one for real values and another one for imaginary values).

Application : 2D-image for a sample channel time-frequency grid with $N_D = 14$ time slots and $N_S = 72$ subcarriers (based on LTE)

Results for DNN model 1

Model 2 Training

Smith and Cox Synchronization

Schmidl and Cox synchronization algorithm uses two repeated training halves, referred to as S&C method.

It estimates the start of each symbol.

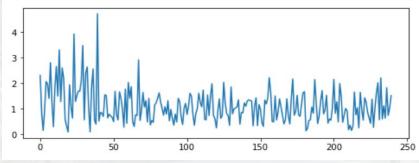

Smith and Cox Synchronization

```
def addSTO(signal, sto):
    return np.hstack([np.zeros(sto), signal])

def addNoise(signal, sigma2): |
    noise = np.sqrt(sigma2/2) * (np.random.randn(len(signal)) + 1j*np.random.randn(len(signal)))
    return signal + noise

def addChannel(signal, h):
    return scipy.signal.lfilter(h, (1,), signal)
```

```
1  x = createFrame(ofdm, qam_preamble=qam_preamble*2)
2  sto = ofdm.K//2
3  r = addNoise(addCFO(x, sto), 0.5)
4  plt.plot(abs(r));
```

Smith and Cox Synchronization

```
# Method 1 to calculate P(d)
 2 d_set = np.arange(0, sto + ofdm.K)
 3 P1 = np.zeros(len(d_set), dtype=complex)
   for i, d in enumerate(d set):
        P1[i] = sum(r[d+m].conj()*r[d+m+ofdm.L] for m in range(ofdm.L))
    plt.plot(d set, abs(P1))

```

Conclusion and future work

In order to change the length of the cyclic-prefix adaptively, we must estimate the T~ normalized RMS delay spread:

$$\hat{\tau}_{\text{RMS}} = \sqrt{\frac{\sum_{n} \left| \hat{h}(n) \right|^{2} n^{2}}{\sum_{n} \left| \hat{h}(n) \right|^{2}} - \left(\frac{\sum_{n} \left| \hat{h}(n) \right|^{2} n}{\sum_{n} \left| \hat{h}(n) \right|^{2}} \right)^{2}}$$

We will change the length of the CP based on the estimation result.
